[Abstract] The enzyme Activation induced deaminase (AID) underpins antibody affinity maturation and isotype switching through its mutagenic activity of deaminating deoxycytidine to deoxyuridine in DNA. Subsequent processing of the deoxyuridine initiates the processes of somatic hypermutation (SHM) and class switch recombination (CSR) in B cells. Structure-function analysis of AID requires sensitive and biologically relevant methods to measure its various activities. Here we describe simple but effective methods to measure 1) the ability of AID to mutate the *Escherichia coli* genome, which provides an indication of its catalytic activity; 2) the capacity of AID to perform SHM by complementing a derivative of the DT40 chicken B cell line; 3) the ability of AID to perform CSR by complementing AID-deficient primary mouse B cells. The combination of the three methods, accompanied by the necessary analysis of AID subcellular localization and protein expression levels and stability, as controls, allows detailed structure-function interrogation of AID.

Part I. Measuring mutagenic activity of AID in *E. coli*

The following procedure has been adapted from Petersen-Mahrt *et al.* (2002). It provides a measurement of the capacity of AID to mutate the *Escherichia coli* genome by selecting for those mutations in the *rpoB* gene that confer resistance to Rifampicin. It can be used as a proxy for the catalytic activity of the enzyme, although it involves deamination of a transcribed gene, which might influence the results. When comparing different AID variants or mutants, it provides a measurement of their mutagenic activity compared to the wt enzyme, which often but not always correlates with the enzymatic activity of the corresponding recombinant enzymes measured on DNA oligonucleotide substrates.

Materials and Reagents

1. Sterile multi-channel basin
2. Competent \square ung *E. coli*. We use the BW310 strain (Duncan, 1985) (a gift from Dr. Bernard Weiss Department of Pathology, Emory University School of Medicine, Atlanta)

3. Plasmids containing AID or AID variants cloned in an inducible prokaryotic expression vector. We use IPTG-inducible pTrcHis vectors (Life Technologies, catalog number: V360-20)
Note: Currently, it is "Thermo Fisher Scientific, Invitrogen™, catalog number: V360-20".
4. Tryptone (BioShop Canada, catalog number: TRP402)
5. Yeast extract (BioShop Canada, catalog number: YEX401)
6. Sodium Chloride (NaCl) (BioShop Canada, catalog number: SOD002)
7. Agar (bacteriological grade) (BioShop Canada, catalog number: AGR001)
8. Na₂HPO₄·7H₂O (BioShop Canada, catalog number: SMP400)
9. Potassium Phosphate Monobasic (KH₂PO₄) (BioShop Canadap, catalog number: PPM666)
10. Ammonium chloride (NH₄Cl) (Sigma-Aldrich, catalog number: A0171)
11. Ampicillin (stock 100 mg/ml in ddH₂O) (BioShop Canada, catalog number: AMP201)
12. Carbenicillin (100 mg/ml in ddH₂O) (BioShop Canada, catalog number: CAR666)
13. Rifampicin (stock 100 mg/ml in DMSO) (Sigma-Aldrich, catalog number: R3501)
14. IPTG (stock 1 M in ddH₂O) (BioShop Canada, catalog number: IPT001)
15. Transparent sterile 96-well plates, flat bottom (Corning, catalog number: 3595)
16. LB media (see Recipes)
17. LB agar (see Recipes)
18. 2x TY media (see Recipes)
19. 5x M9 media (see Recipes)

Equipment

1. Bunsen burner
2. Sterile glass beads (for bacteria plating) (Genlantis, EZ-spread, catalog number: C400050)
3. 37 °C incubator (for bacterial plates)
4. 37 °C incubator with shaker (for bacterial cultures)
5. 42 °C water bath
6. Hand counter
7. Multichannel pipettor

Procedure

Prepare as many 10 cm LB agar plates supplemented with rifampicin (100 µg/ml) + ampicillin (100 µg/ml) as samples will be tested (selection plates). Prepare also the necessary number of LB agar plates supplemented with ampicillin (100 µg/ml) for the initial transformation and for viability plates in the experiment (see below). For example, to compare 3 constructs prepare 3

plates supplemented with ampicillin for bacterial transformation plus $3 \times 5 = 15$ plates supplemented with ampicillin for the assay (for a total of 18 ampicillin plates), as well as 15 plates supplemented with rifampicin + ampicillin.

A. Day 1: Transformations

1. For each construct, mix 50 ng DNA with 50 μ l competent BW310 in a sterile 1.5 ml Eppendorf tube.
2. Incubate tube on ice for 30 min.
3. Heat shock for 45 sec at 42 °C in a water bath.
4. Return tube to ice for 5 min.
5. Recover bacteria by transferring the whole volume of bacteria to a 1.5 ml Eppendorf tube containing 950 μ l 2x TY media and place in shaking incubator at 230 rpm for 45 min at 37 °C.
6. Plate 40 μ l of each bacterial culture from point 5 onto LB-ampicillin plates and incubate at 37 °C overnight.

B. Day 2: Picking colonies and inducing AID expression

1. Pick at least 5 isolated colonies from each transformation plate (i.e. construct) into a 15 ml tube containing 1.5 ml LB media supplemented with 100 μ g/ml carbenicillin and 1 mM IPTG.
2. Grow overnight at 37 °C.

C. Day 3: Plating

1. Selection plates

- a. Plate 50 μ l of each induced culture in 10 cm Petri dishes with LB rifampicin + ampicillin.
- b. Incubate ~48 h at 37 °C until colonies are clearly visible.

Note: That colony sizes can be heterogeneous, as different mutations will allow different growth rates in rifampicin. In addition, hypo- or hyperactive AID variants may require ad hoc plating (i.e. larger volumes or diluting the sample, respectively) to obtain a number of colonies that can be accurately counted. Do not plate volumes smaller than 50 μ l to prevent too rapid absorption and clustering of the colonies.

2. Viability plates

- a. Make 10-fold serial dilutions of the induced cultures in 1x M9 media using a sterile 96-well plate and a multichannel pipettor for convenience. Dilute up to 10^{-6} .
- b. Plate 50 μ l of the 10^{-6} in 10 cm petri dish LB ampicillin.

Note: Depending on the conditions of growth, induction and expression, other dilutions (10^{-4} or 10^{-5}) may be necessary to obtain a number of colonies that can be easily and accurately counted (Figure 1).

- c. Incubate overnight at 37 °C.
- D. Day 4: Count LB ampicillin plates

- E. Day 5: Count LB rifampicin plates

Note: Count all colonies. In the case of rifampicin plates count colonies of all sizes. If there are too many colonies, (i.e., small and close together) 1/2-1/4 of the plate could be counted to estimate the total number of colonies without affecting the accuracy of the measurement, as long as isolated colonies can be distinguished. If colonies are confluent repeat the experiment, do not replate cultures that were kept overnight since viability diminishes significantly. If there are too few or no colonies the measurement may not be accurate; repeat and adjust the volume or dilution to plate accordingly.

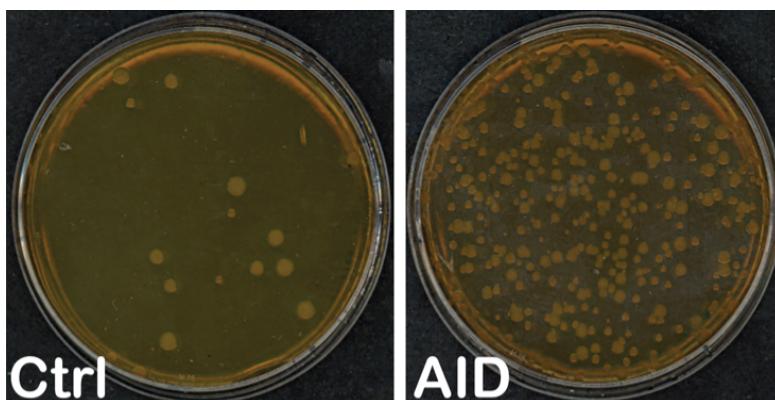

Figure 1. Example of LB ampicillin + rifampicin plates incubated at 37 °C for two days with bacteria transformed with pTrc-His (Ctrl) and pTrc-His-AID (AID)

- F. Calculating *rpoB* mutation frequency

1. For each culture calculate the number (N) of Colony Forming Unit (CFU) per ml using the formula

$$N = (n \times d \times V_o) / V_p$$

n: Number of colonies counted in the plate; d: Dilution factor; V_o: Original culture volume (μl); V_p: Plated volume (μl)

The LB ampicillin plate will provide the viable CFU/ml (N_V) and the LB rifampicin plate will provide the mutant CFU/ml (N_M)

2. Calculate the number of Rifampicin resistant (RIF^R) mutants per /10⁹ CFU as:

$$RIF^R / 10^9 = \frac{N_M}{N_V} \times 10^9$$

Calculate the median RIF^R/10⁹ of all the values obtained for each construct and evaluate significance using the appropriate statistical method depending on the number of samples compared. At least 3 independent experiments with 5 colonies per construct are necessary for accurate comparisons of relative frequencies between AID

variants.

Recipes

Note: Media must be autoclaved after preparation and kept sterile.

1. LB media (for 1 L in ddH₂O)
10 g tryptone
5 g yeast extract
5 g NaCl
2. LB agar (for 1 L in LB media)
LB media
15 g agar
3. 2x TY media (for 1 L in ddH₂O)
16 g tryptone
10 g yeast extract
5 g NaCl
4. 5x M9 media (for 1 L in ddH₂O)
64 g Na₂HPO₄·7H₂O
15 g KH₂PO₄
2.5 g NaCl
5 g NH₄Cl

Part II. Measuring somatic hypermutation activity of AID in DT40 cells

DT40 cells are a chicken B cell lymphoma line that constitutively expresses IgM at the plasma membrane, as well as AID (Arakawa *et al.*, 2002). Chickens diversify their Ig genes by gene conversion, a homologous recombination-based mechanism. However, the DT40-derived cell line used here (DT40 ΔΨV IgM⁺) has been engineered to eliminate the V pseudogenes that act as homology donors for gene conversion, causing that AID deaminations accumulate as mutations, mostly at C:G pairs with a bias towards transversion mutations (Arakawa *et al.*, 2004). The protocol below takes advantage of the fact that a fraction of AID-induced mutations at the Ig loci will disrupt IgM expression. This can be quantified by flow cytometry as IgM-loss cells, and is a convenient proxy to monitor SHM frequency. When starting from a DT40 ΔΨV IgM⁺ population, the proportion of IgM-loss cells is a function of the time the cells spent in culture as well as of the SHM frequency, which depends directly on AID activity. A DT40 ΔΨV IgM⁺ line in which AID expression has also been eliminated by knock out (KO) can be complemented with expression vectors encoding AID or AID mutants, either tagged with GFP or linked to GFP expression by an internal ribosomal entry site, in order to compare their relative ability for SHM. GFP expression is used to monitor infection efficiency and to evaluate IgM-loss on infected cells only.

Materials and Reagents

1. 6-well plate, sterile and tissue-treated (Corning, catalog number: 3516)
2. 24-well plate, sterile and tissue-treated (Corning, catalog number: 3526)
3. 96-well plate, round-bottom, sterile and tissue-treated (Corning, catalog number: 3799)
4. 15 ml sterile conical tubes
5. 1.5 ml Eppendorf tubes
6. 5 ml round-bottom tubes (facs tube)
7. HEK 293T cells (ATCC, catalog number: CRL-3216)
8. DT40 AID KO Δ ΨV IgM⁺ cells (these are non adherent cells) (Arakawa et al., 2004) (a gift from Dr. J-M Buerstedde, National University of Ireland, Galway)
9. DMEM culture media (Wisent, catalog number: 319-005-CL)
10. RPMI 1640 culture media (Wisent, catalog number: 350-000-CL)
11. FBS (Wisent, catalog number: 080150)
12. Chicken serum (Life Technologies, Gibco®, catalog number: 16110-082)
Note: Currently, it is "Thermo Fisher Scientific, Gibco™, catalog number: 16110-082".
13. Penicillin-Streptomycin (Wisent, catalog number: 450-201-EL)
14. β -Mercaptoethanol (BioShop Canada, catalog number: MER002)
15. TransIT-LT1 reagent (Mirus Bio LLC, catalog number MIR 2305)
16. Polybrene (8 mg/ml in water) (Sigma-Aldrich, catalog number: H9268)
17. HEPES 1 M (Wisent, catalog number: 330-050-EL)
18. Mouse Anti-Chicken IgM-PE (SouthernBiotech, catalog number: 8310-09)
19. PBS (1x) (BioShop Canada, catalog number: PBS404)
20. BSA (BioShop Canada, catalog number: ALB001)
21. Expression vector encoding the VSV G envelop protein (pVSVG)
22. Expression vector encoding for MLV polyprotein and reverse transcriptase (pGagPol)
23. Retroviral expression vector containing AID variants and selection or reporter marker (we use pMXs-ires-GFP)
24. Direct PCR Lysis reagent (VIAGEN BIOTECH, catalog number: 301-C)
25. Proteinase K (stock 10 mg/ml in water at -20 °C) (Bio Basic Canada Inc., catalog number: PB0451)
26. KOD (Merck Millipore Corporation, Novagen, catalog number: 71086-3) or Pfu Turbo (Agilent, catalog number: 600250-52) high fidelity DNA polymerase
27. Any Taq DNA polymerase for A-tailing
28. QiaexII gel purification Kit (QIAGEN, catalog number: 20021)
29. pGEMT easy (Promega Corporation, catalog number: A1360)
30. Complete DMEM media (see Recipes)
31. Complete DT40 media (see Recipes)

Equipment

1. 40 μ m cell strainer
2. Centrifuge
3. 37 °C, 5% CO₂ cell culture incubator
4. Flow cytometer
5. PCR machine
6. Oven
7. Vortex (Scientific industries, model: Vortex-genie 2)

Procedure

A. Day 1: Plating HEK 293T cells for retrovirus packaging

Plate 0.5 \times 10⁶ cell/well in a 6-well plate in 2 ml complete DMEM media. At the moment of plating, cells should be 75-90% confluent.

B. Day 2: HEK 293T transfection

1. Prepare the following for each well of cells to be transfected:
2. Mix the following in this order in a 1.5 ml Eppendorf tube by gentle tapping at room temperature:

RPMI 1640 (without additives) 250 μ l

TransIT-LT1 reagent 7.5 μ l

Mix well and then add:

pGagPol 0.625 μ g

pVSVG 0.625 μ g

Retroviral vector 1.25 μ g

Note: The indicated masses of the plasmids are for achieving a molar DNA ratio of 1 [pVSVG]: 1 [pGagPol]: 2 [Retroviral vector], adjust the masses according to your plasmid sizes.

3. Let sit 20 min then add to the cells dropwise.
4. Rock the plate gently and incubate at 37 °C.

C. Day 3

1. Carefully remove media from each well of transfected HEK 293T cells.
2. Add 2 ml complete DT40 media supplemented with 10 mM HEPES to each well.

D. Day 4: DT40 infection

1. Transfer the media (viral supernatant) from each transfected HEK 293T cells well to a 15 ml conical tube. Centrifuge at 200 \times g, 5 min at room temperature.

2. In a 24-well plate, plate 1×10^6 DT40 cells/well in 500 μl DT40 media (Cells growing exponentially and harvested at a density of $\sim 0.5\text{-}1 \times 10^6$ cells/ml should be used).
3. Add 1.5 ml/well of centrifuged viral supernatant to the plated DT40 cells.
4. Add Polybrene to 8 $\mu\text{g}/\text{ml}$ and HEPES to 10 mM final concentrations to each well.
5. Centrifuge the plate at $600 \times g$ for 1.5 h at 32 °C.
6. Place the plate for 4 h in the cell culture incubator (37 °C, 5% CO₂).
7. After 4 h, remove media from each well and add 2 ml DT40 media supplemented with 10 mM HEPES.
8. GFP infection frequency can be checked by flow cytometry and sorted 24-48 h later. The expected efficiency is $\sim 40\text{-}90\%$, depending on the construct.

E. Sorting

Note: Work in sterile conditions.

1. For each sample, prepare 1 to 4 round-bottom 96-well plates containing 200 $\mu\text{l}/\text{well}$ of filtered complete DT40 media.

Note: The number of plates will depend on the number of cells sorted per well, for single cell deposition prepare 4 plates to account for cloning efficiency, for 5 cells/well two plates are enough, for >5 cells/well one plate will be enough to obtain sufficient populations for the fluctuation analysis.

2. Transfer 10^7 infected cells into a sterile FACS tube.
3. Centrifuge $200 \times g$, 5 min at 4 °C.
4. Wash with 4 ml PBS and centrifuge $200 \times g$, 5 min at 4 °C.
5. Add anti-chicken IgM-PE (1:200) in 200 μl PBS-1%BSA.
6. Mix well by vortexing gently and incubate for 30 min on ice and in the dark.
7. Wash cells with 4 ml PBS and centrifuge $200 \times g$, 5 min at 4 °C.
8. Resuspend cells in 300 μl PBS and filter the sample through a 40 μm cell strainer.
9. Sort 1-3,000 cells/well (GFP⁺, IgM⁺).

Note: The number of cells sorted in each well will depend on the application. The fluctuation analysis for surface IgM-loss will show less variation when the initial populations are large. However, when subsequently analyzing V region sequences, all shared mutations should be removed to prevent biasing by clonal expansion of pre-existing mutations. Using 1 cell per well will yield single cell clones, which have larger variations in the fluctuation analysis but allow a more accurate analysis of SHM upon sequencing. A larger number of clones should be analyzed in this case to obtain accurate median values of IgM-loss.

F. Identifying clones/populations

1. Clones/populations will be visible at naked eye 3-5 d after sorting and should be transferred to a 24-well plate containing 1 ml of filtered complete DT40 media. Isolate 12-24 clones/populations for each transduced construct (see Note above).

2. When cells get confluent (3-4 days after isolating the clones), add 1 ml DT40 media to each well.
3. Dilute 1:2 by carefully resuspending the cells using a P1000 and swirling around. Remove 1 ml of cells, then add 1 ml of fresh DT40 media to each well, everyday, for 2-4 weeks.

Note: Monitor cell density by looking at the cells every day. Certain conditions or AID variants may slow down proliferation. Dilution of the cells and the length of expansion should be adjusted accordingly. The frequency of IgM should increase with time; the total time of expansion will depend on the signal to noise ratio of each particular experiment.

G. Flow cytometry for surface IgM

1. Transfer 500 μ l of cells from each well to a flow cytometry tube.
2. Centrifuge 200 \times g, 5 min at 4 °C.
3. Wash with 4 ml PBS and centrifuge 200 \times g, 5 min at 4 °C.
4. Add anti-chicken IgM-PE (1:200) in 100 μ l PBS-1% BSA.
5. Mix well by vortexing and let sit for 30 min (on ice and in the dark).
6. Wash with 4 ml PBS and centrifuge 200 \times g, 5 min at 4 °C.
7. Resuspend in 300 μ l PBS.
8. Analyze samples in a flow cytometer. Acquire 20,000 events. Always have a mixture of IgM⁺ and IgM⁻ DT40 cells as controls to set the gating (Figure 2).
9. Analyze IgM-loss % for each clone and calculate median values for each construct or condition. Analyze statistically.

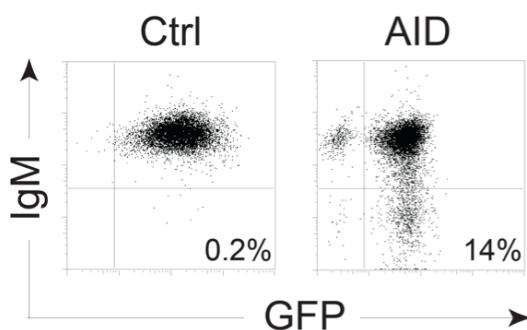

Figure 2. Example of DT40 AID KO Δ V_L IgM⁺ cells expressing control vector or pMXs-AID-ires-GFP expanded for 3 weeks and stained for IgM

H. Variable region sequencing

The following procedure is for amplifying and sequencing the IgV_L region from each DT40 subpopulation. If no phenotypic selections are applied, many sequences will be unmutated. The number of mutations over the total number of bases sequenced will provide an accurate estimation of the mutation frequency. However, obtaining sufficient (>50)

independent mutations to evaluate changes in the mutation patterns may require extensive sequencing. Calculating mutation rates will additionally require to measure the doubling time of the cells and record the total number of population doublings during the expansion of the cells. On the other hand, IgM-loss cells can be purified by FACS, which will select cells bearing more mutated sequences on average. The latter is better suited for analyzing mutation patterns but less accurate to calculate mutation frequency.

I. DNA extraction

1. Prepare DNA extraction buffer (485 μ l Direct PCR + 15 μ l 10 mg/ml Proteinase K).
Note: Direct PCR needs to be warmed up and make sure any precipitates go back in solution before using.
2. Spin 5 \times 10⁴ to 5 \times 10⁵ cells for 15 sec at max speed in the tabletop microcentrifuge.
3. Carefully remove the supernatant.
4. Resuspend cells gently in 50 μ l DNA extraction buffer by pipetting up and down.
5. Incubate for 5 h at 55 °C. Use an oven rather than a heat block to prevent condensation on the lid (this step can be done overnight).
6. Incubate for 45 min at 85 °C to inactivate the Proteinase K.
7. Store DNA at -20 °C or proceed to PCR.

J. PCR reaction

1. Use 1-5 μ l DNA template from above as template.
2. Primers:
5'-gcggggccgtcactgattggcc -3'
5'-ccccagcctgcccagaatccaag -3'
3. PCR has to be made with high fidelity DNA polymerase (such as KOD or Pfu turbo). Use all reagents and concentrations as suggested in the polymerase's instructions.
4. Perform PCR in 50 μ l final volume.
Note: Always include a no template control, using some of the left over DNA extraction buffer instead, which controls for possible reagents contamination.
5. Annealing temperature: perform a touch down PCR of 8 cycles at 68-60 °C followed by 23 cycles at 60 °C for annealing temperatures. Extension time and temperature, as well as denaturing temperature, will depend on the DNA polymerase used. The expected PCR product is 520 base pairs.

K. Cloning and sequencing

Note: From here on keep away from the PCR hood to avoid contaminations with final product in future experiments.

1. Run 50 μ l of the PCR product in an agarose gel. A single band of 520 bp should be visible and no band should be visible in the water control.
2. Gel purify following QIAEX II kit instructions.

3. Elute the purified fragment in 20 μ l of 10 mM Tris pH 8.
4. Cloning in T-vector (alternatively, restriction sites could be added to the oligonucleotides or use your cloning method of choice).

Poly-A tailing (high fidelity polymerase do not add A-overhangs):

Purified PCR product from step K3	17 μ l
10x DNA pol buffer with Mg ²⁺ (2.5 mM Mg ²⁺ final)	2 μ l
10 mM dATP (0.2 mM final)	0.4 μ l
Taq DNA Polymerase	1 μ l

Incubate for 20 min at 72 °C in PCR cycler.

5. Immediately ligate into pGEM-T easy following the protocol provided by the manufacturer.
6. Transform the ligation in *E. coli* DH5 α competent bacteria.
7. Perform minipreps to purify vectors containing cloned PCR products and sequence using Sp6 primer. The total number of sequences to analyze will depend on the average mutation load per sequence and the aim of the experiment.

Recipes

1. Complete DMEM media
 - DMEM
 - FBS 10%
 - Penicillin-Streptomycin 1%
2. Complete DT40 media
 - RPMI 1640
 - FBS 10%
 - FCS 1%
 - β -Mercaptoethanol 100 μ M
 - Penicillin-Streptomycin 1%

Part III. Measuring AID class switch recombination activity

This method uses retroviral complementation of primary B cells obtained from the spleen of AID-deficient (*Aicda*^{-/-}) mice, to assay the capacity of AID variants to produce CSR.

Materials and Reagents

1. 6-well plate, sterile and tissue-treated (Corning, catalog number: 3516)
2. 24-well plate, sterile and tissue-treated (Corning, catalog number: 3526)
3. 12-well plate, sterile and tissue-treated (Corning, catalog number: 3513)

4. 50 ml sterile conical tubes
5. 15 ml sterile conical tubes
6. 1.5 ml Eppendorf tubes (Eppendorf or similar)
7. 10 ml flat syringe plunger
8. 5 ml pipettes
9. 5 ml round-bottom tubes (Falcon®, catalog number: 352008)
10. 70 µm cell strainer (Corning, catalog number: 352350)
11. 40 µm cell strainer
12. PLAT-E ecotropic retrovirus packaging cells (Morita *et al.*, 2000) (a gift from Dr. T Kitamura, University of Tokyo, Japan)
13. *Aicda*^{-/-} mice (Muramatsu *et al.*, 2000) (a gift from Dr. Tasuku Honjo, Kyoto University, Japan)
14. Retroviral vector encoding AID variants (such as pMX-ires-GFP or pMIG)
15. RPMI 1640 culture media (Wisent, catalog number: 350-000-CL)
16. FBS (Wisent, catalog number: 080150)
17. Penicillin-Streptomycin (Wisent, catalog number: 450-201-EL)
18. β -Mercaptoethanol (BioShop Canada, catalog number: MER002)
19. TransIT-LT1 transfection reagent (Mirus Bio LLC, catalog number: MIR 2305)
20. PBS (1x) (BioShop Canada, catalog number: PBS404)
21. BSA (BioShop Canada, catalog number: ALB001)
22. EDTA (BioShop Canada, catalog number: EDT001)
23. Lympholyte-M (Cedarlane Labs, catalog number: CL5031)
24. MACS anti-CD43 microbeads (Miltenyi Biotec, catalog number: 130-049-801)
25. Anti-mouse CD180 (BD, Pharmingen, catalog number: 552128)
26. HEPES 1M (Wisent, catalog number: 330-050-EL)
27. Polybrene (stock resuspended at 8 mg/ml in ddH₂O) (Sigma-Aldrich, catalog number: H9268)
28. LPS (stock resuspended at 1 mg/ml in RPMI without additives stored at -20 °C) (Sigma-Aldrich, catalog number: L-4391)
29. Recombinant murine IL-4 (stock resuspended at 5 µg/ml, in PBS + BSA 0.1% stored at -20 °C) (PREPROTECH, catalog number: 214-14)
30. Recombinant human TGF-β1 (stock resuspended at 1 µg/ml in 4 mM HCl + 1 mg/ml BSA stored at -20 °C) (R&D Systems, catalog number: 240-B)
31. FcR Blocking Reagent, mouse (Miltenyi Biotec, catalog number: 130-092-575)
32. Biotinylated Rat Anti-Mouse IgG1 (BD, Pharmingen, catalog number: 553441)
33. Biotinylated Rat Anti-Mouse IgG3 (BD, Pharmingen, catalog number: 553401)
34. Biotinylated Rat Anti-Mouse IgG2b (BD, Pharmingen, catalog number: 553393)
35. Anti-biotin-APC (Miltenyi Biotec, catalog number: 130-090-856)

36. Propidium Iodide (stock resuspended at 100 mg/ml in ddH₂O, stored protected from light at 4 °C) (BioShop Canada, catalog number: PPI777)
37. Complete RPMI media (see Recipes)
38. MACS column buffer (see Recipes)

Equipment

1. Centrifuge
2. 37 °C, 5% CO₂ tissue culture incubator
3. AutoMACS Pro Separator (Miltenyi Biotec, catalog number: 130-092-545)
4. Flow cytometer

Procedure

Note: All procedures are performed in a tissue culture hood to prevent contaminations.

A. Day 1: Plating PLAT-E cells

Plate 0.5 x 10⁶ cell/well in a 6-well plate in 2 ml complete RPMI media.

Note: At the moment of plating, cells should be 75-90% confluent. The quality of the cells will highly impinge on the transfection frequency and thereby on retroviral production for infection.

B. Day 2: PLAT-E transfection and purification of splenic *Aicda*^{-/-} B cells

Transfection

1. Mix the following in this order in a 1.5 ml Eppendorf tube by gentle tapping at room temperature:

RPMI 1640 no addition 250 µl

TransIT-LT1 reagent 7.5 µl

Mix well and then add:

Retroviral plasmid 2.5 µg

2. Let sit 20 min then add to the Plat-E cells dropwise. Rock the plate gently and incubate at 37 °C.

B cell purification

1. Sacrifice *Aicda*^{-/-} mice and extract the spleen using sterile utensils and place into a well of a 6-well plate containing sterile PBS.

Note: From here on working in the cell culture hood. A filmed example of the procedure to remove the spleen and extracting the lymphocytes by the method described in points 2-4 below has been previously published (Zaheen and Martin, 2010).

2. Put the spleen on a 70 μ m cell strainer placed on top of a 50 ml falcon. Add 1 ml complete RPMI media onto the spleen and gently press using the flat end of a 10 ml flat syringe plunger.
3. Add complete RPMI media 1 ml at a time and continue squishing the spleen until all the cells have been extracted from the organ (should only be left with clear tissue on the strainer and lead to a final volume of 5 ml).
4. Pipette up and down gently with a 5 ml pipette to produce a homogeneous suspension and transfer cells to a 15 ml conical tube.
5. Introduce a sterile, long Pasteur pipette in the tube.
6. Slowly pipette 3 ml of Lympholyte-M into the Pasteur pipette to underlay the cell suspension.
7. Handle the tube gently to avoid disturbing the phases
8. Centrifuge 1,250 \times g for 20 min at RT-with no break.

Note: Brake must be turned off in order to maintain the lymphocyte interphase.

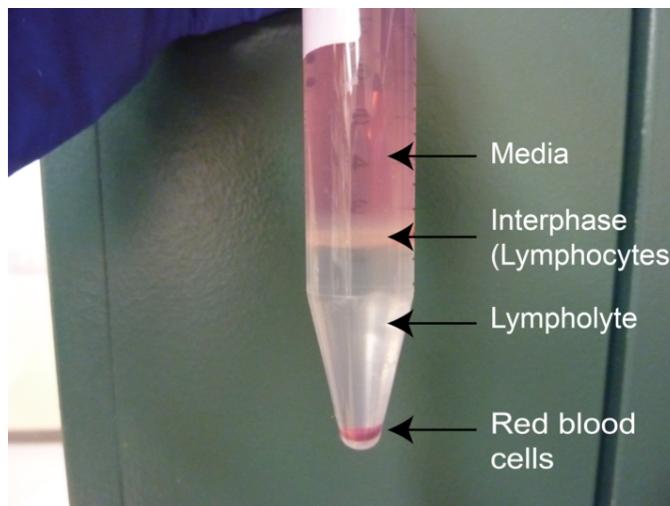

Figure 3. Typical aspect of the lymphocyte-rich interphase between medium and lympholyte after centrifugation

9. Collect the interphase using a 5 ml pipette, avoiding as much Lympholyte-M as possible. Tilt the 15 ml conical tube and place the tip of the pipette slightly on top of the interphase, touching the side of the canonical tube. Aspirate gently avoiding as much of the Lympholyte phase as possible (Figure 3).
10. Resuspend the cells by pipetting up and down a few times in 15 ml PBS 1% BSA.
11. Centrifuge 800 \times g for 10 min at RT-break is ok now.
12. Resuspend the cells in 15 ml PBS 1% BSA.
13. Centrifuge 400 \times g for 10 min at RT.
14. Resuspend in 100 μ l PBS 1% BSA.
15. Add anti-CD43 microbeads. Use 20 μ l per spleen.

Note: Resting B cells are CD43. Depleting the splenic cell suspension of CD43⁺ cells will eliminate most T and activated B cells (note that this protocol is very inefficient in extracting dendritic cells or macrophages). A typical purity of >90% naïve B cells is achieved.

16. Incubate 45 min at 4 °C mixing gently every now and then.
17. Add 15 ml of cold PBS 1% BSA.
18. Centrifuge 400 x g for 10 min at 4 °C.
19. Resuspend in 1 ml MACS column buffer and pass the cells through a 40 µm cell strainer to avoid cell clumps in the AutoMACS.
20. Proceed to AutoMACS separator and use DEPLET program with quick washes in between samples.

Note: Remember this is a depletion of activated cells (i.e., you want the cells that flow through, not the retained ones).

21. Collect the flow through cells from the AutoMACS and wash with cold PBS 1% BSA, then centrifuge 400 x g for 10 min at 4 °C.
22. Resuspend in 1 ml complete RPMI media.
23. Count the cells (do a 1/20 dilution in PBS and then 1/2 with trypan blue).

Note: The quality of the depletion could be monitored by flow cytometry using anti-CD43 and anti-B220 markers. Typically, this procedure yields >90% pure resting B cells.

24. Plate 10⁶ B-cells per well in a 24-well plate in 1 ml complete RPMI media. Plate as many wells as constructs you want to test + one well as uninfected control.
25. Add 1 ml of medium containing 0.5 µg/ml anti-CD180 (final concentrations of 0.5 x 10⁶ B cells/ml and 0.25 µg/ml anti-CD180). Anti-CD180 antibody promotes B cell proliferation without inducing AID expression or CSR.
26. Put cells in the tissue culture incubator.

C. Day 3

Observe the cells, B cells should start to proliferate and clump. Remove media from transfected PLAT-E cells and add 2.5 ml fresh RPMI media supplemented with 10 mM HEPES.

D. Day 4: B cell infection

1. Transfer the viral supernatant from transfected PLAT-E cells to a 15 ml conical tube. Centrifuge at 200 x g, 5 min at room temperature.
2. Transfer viral supernatant to a new tube.
3. Adjust the concentration of viral supernatant to 20 mM HEPES and 16 µg/ml Polybrene.

4. Remove 1 ml media from the top of each well containing B cells avoiding disturbing the cells, and add 1 ml of supplemented viral supernatant for a final concentration of 8 μ g/ml Polybrene and 10 mM HEPES.
5. Centrifuge the 24-well plate at 515 \times g for 1.5 h at 30 °C.
6. Place the plate for 4 h in the tissue culture incubator at 37 °C.
7. After 4 h remove most of the media from each well, and add 2 ml complete RPMI media containing appropriate mitogens and cytokines as follows.
For IgG1 switching: 5 μ g/ml LPS + 25 ng/ml IL-4 (for saturating conditions) or 5 μ g/ml LPS + 5 ng/ml (for non-saturating conditions)
For IgG3 switching: 25 μ g/ml LPS
For IgG2b switching: 5 μ g/ml LPS (+TGF- β 1 next day, see below)

E. Day 5: For IgG2b, add 1 ng/ml TGF- β 1 (it is added 24 h after infection because it delays proliferation)

F. Day 6: For IgG1 or IgG3, transfer cells to a 12-well plate and add 2 ml of fresh RPMI (no cytokines needed). For IgG2b leave cells alone.

G. Day 7: Measure class switch recombination to IgG1 or IgG3 (Figure 4)

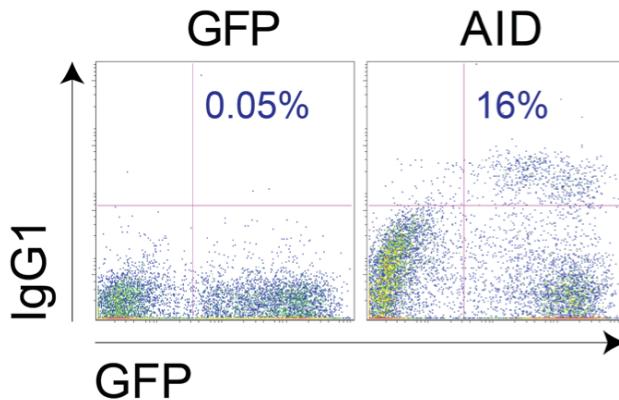

Figure 4. Example of *Aicda*^{-/-} B cells transduced with vector control or pMXs-AID-ires-GFP and stimulated as explained above

H. Day 8: Measure class switch recombination to IgG2b if desired

Measuring Class Switch Recombination:

1. Resuspend the cells GENTLY and transfer 500 μ l of cells into FACS tubes.
2. Top up tube with PBS and centrifuge at 400 \times g for 5 min at 4 °C.
3. Block by incubating cells in 100 μ l PBS 1% BSA containing 1:10 dilution of FcR block for 10 min at 4 °C.

4. Add 100 μ l PBS 1% BSA containing 1:100 dilution of anti-IgG1/anti-IgG3 or 1:50 dilution of anti-IgG2b.
5. Incubate at 4 °C for 30 min.
6. Top up the tube with cold PBS and centrifuge at 400 $\times g$ for 10 min at 4 °C.
7. Resuspend cells in 100 μ l of anti-biotin-APC at 1:50 dilution in PBS 1% BSA by gently vortexing.
8. Incubate 10 min at 4 °C in the dark.
9. Top up the tube with cold PBS and centrifuge 400 $\times g$ for 10 min at 4 °C.
10. Resuspend the cells in 200 μ l PBS.
11. Bring to flow cytometer.
12. Add 5 μ l of 100 μ g/ml propidium iodide per tube to exclude dead cells.

Note: Infection efficiency can be affected by the AID variant used. With wild type AID in pMX-ires-GFP we typically obtain ~40-60% infection efficiency and ~20% switching to IgG1 among the GFP⁺ cells.

Recipes

1. Complete RPMI media
RPMI 1640
10% FBS
100 μ M β -Mercaptoethanol
1% Penicillin-Streptomycin
2. MACS column buffer
PBS
0.5% BSA
2 mM EDTA

Acknowledgements

The protocols described here were adapted from our publications (Methot *et al.*, 2015; Zahn *et al.*, 2014). Our studies are supported in part by the Canadian Institutes of Health Research, the Cancer Research Society Inc and a Canada Research Chair tier 2 to JMDN. LCL is supported in part by a Cole Foundation Fellowship and SPM is supported by a fellowship from Fonds de recherche Quebec-Santé (FRQ-S).
